The latest generation of adversarial image attacks is, uh, somewhat simpler to carry out [openai.com/blog/multimoda...](https://openai.com/blog/multimodal-adversarial-attacks)

Attacks in the wild

We refer to these attacks as *typographic attacks*. We believe attacks such as those described above are far from simply an academic concern. By exploiting the model's ability to read text robustly, we find that even *photographs of hand-written text* can often fool the model. Like the Adversarial Patch,²² this attack works in the wild; but unlike such attacks, it requires no more technology than pen and paper.

Attack text label iPod ▾

Granny Smith	85.6%
iPod	0.4%
library	0.0%
pizza	0.0%
toaster	0.0%
dough	0.1%

Granny Smith	0.1%
iPod	99.7%
library	0.0%
pizza	0.0%
toaster	0.0%
dough	0.0%

When we put a label saying "iPod" on this Granny Smith apple, the model erroneously classifies it as an iPod in the zero-shot setting.

Decoder

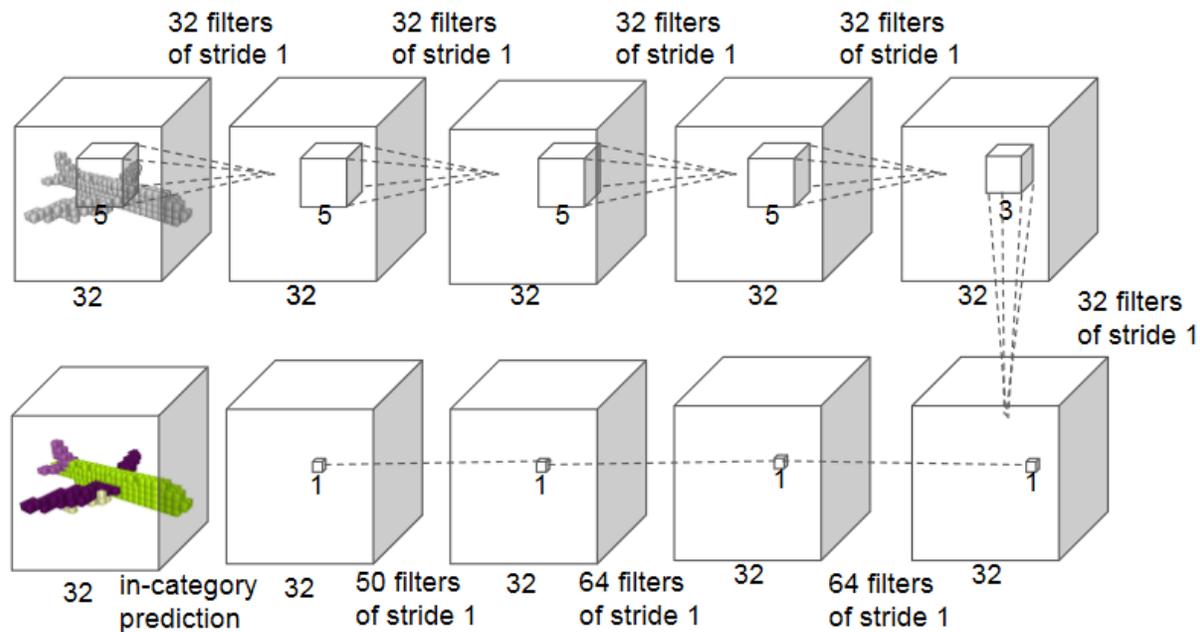

Figure 10. **Baseline 3D CNN** segmentatic network is fully convolutional and predicts p voxel.

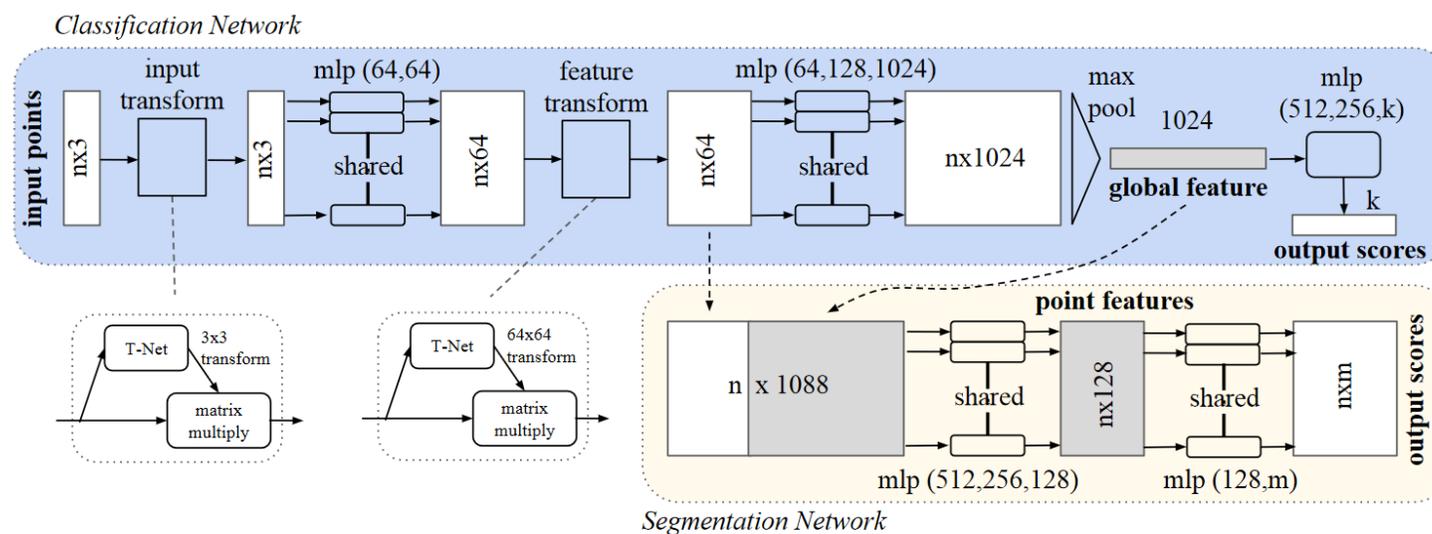

Figure 2. **PointNet Architecture.** The classification network takes n points as input, applies input and feature transformations, and then aggregates point features by max pooling. The output is classification scores for k classes. The segmentation network is an extension to the classification net. It concatenates global and local features and outputs per point scores. “mlp” stands for multi-layer perceptron, numbers in bracket are layer sizes. Batchnorm is used for all layers with ReLU. Dropout layers are used for the last mlp in classification net.

Abstract

The dominant sequence transduction models are based on complex recurrent or convolutional neural networks that include an encoder and a decoder. The best performing models also connect the encoder and decoder through an attention mechanism. We propose a new simple network architecture, the Transformer, based on the self-attention mechanism.

$$\text{Attention}(Q, K, V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V$$

Input: LSC is the best!

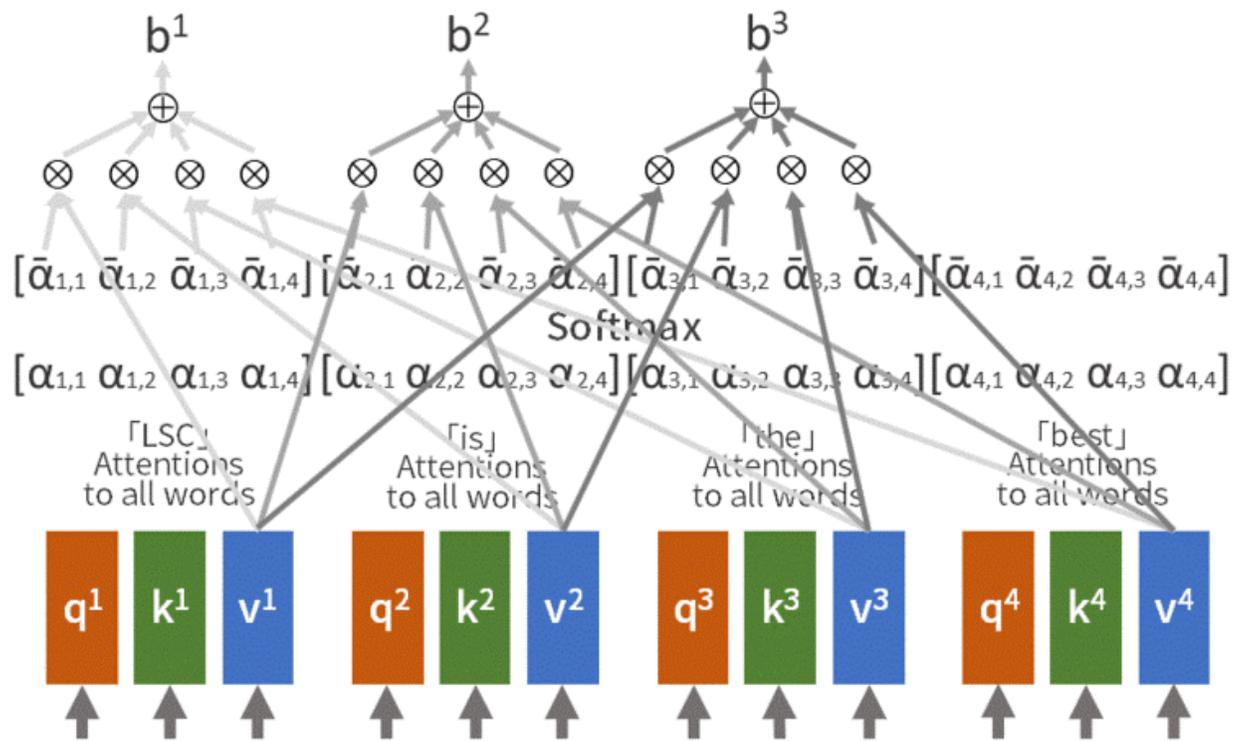

$$\alpha_{i,j} = \frac{q^i \cdot k^j}{\sqrt{d}}$$

d: dimension of q, k

A =

$$\begin{bmatrix} \alpha_{1,1} & \alpha_{1,2} & \alpha_{1,3} & \alpha_{1,4} \\ \alpha_{2,1} & \alpha_{2,2} & \alpha_{2,3} & \alpha_{2,4} \\ \alpha_{3,1} & \alpha_{3,2} & \alpha_{3,3} & \alpha_{3,4} \\ \alpha_{4,1} & \alpha_{4,2} & \alpha_{4,3} & \alpha_{4,4} \end{bmatrix}$$

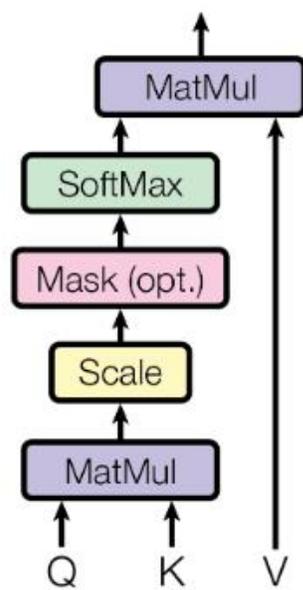

Attention Matrix

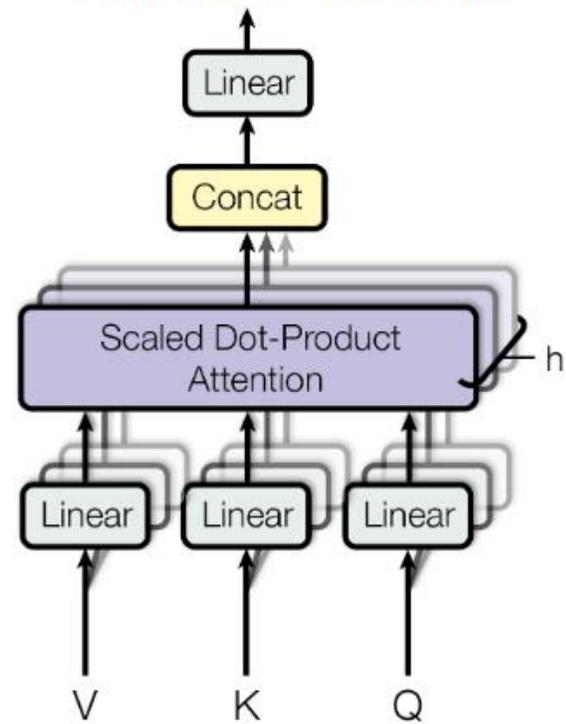

$$b^i = \sum_j \bar{\alpha}_{i,j} v^j$$

Layer Type	Complexity per Layer	Sequential Operations	Maximum Path Length
Self-Attention	$O(n^2 \cdot d)$	$O(1)$	$O(1)$
Recurrent	$O(n \cdot d^2)$	$O(n)$	$O(n)$
Convolutional	$O(k \cdot n \cdot d^2)$	$O(1)$	$O(\log_k(n))$

Scaled Dot-Product Attention

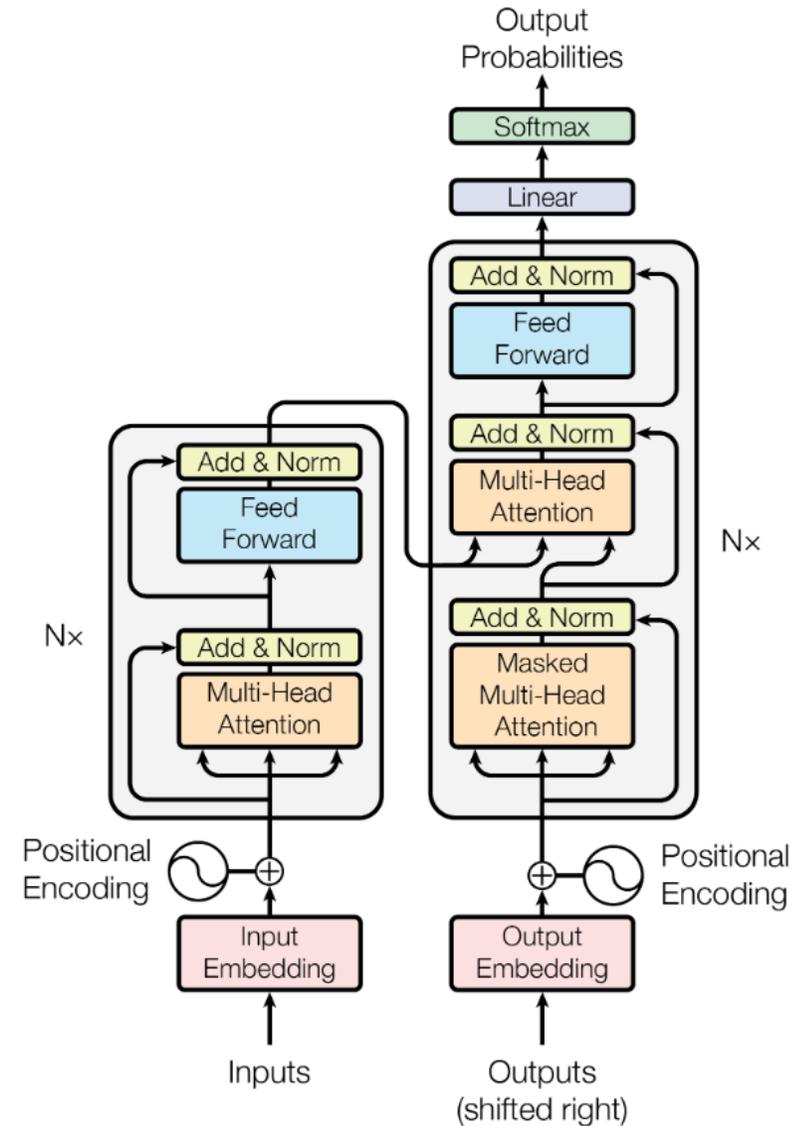

Multi-Head Attention

Transformer Architecture

ABSTRACT

While the Transformer architecture has become the de-facto standard for natural language processing tasks, its applications to computer vision remain limited. In vision, attention is either applied in conjunction with convolutional networks, or used to replace certain components of convolutional networks while keeping their overall structure in place. We show that this reliance on CNNs is not necessary and a pure transformer applied directly to sequences of image patches can perform very well on image classification tasks. When pre-trained on large amounts of data and transferred to multiple mid-sized or small image recognition benchmarks (ImageNet, CIFAR-100, VTAB, etc.), Vision Transformer (ViT) attains excellent results compared to state-of-the-art convolutional networks while requiring substantially fewer computational resources to train.

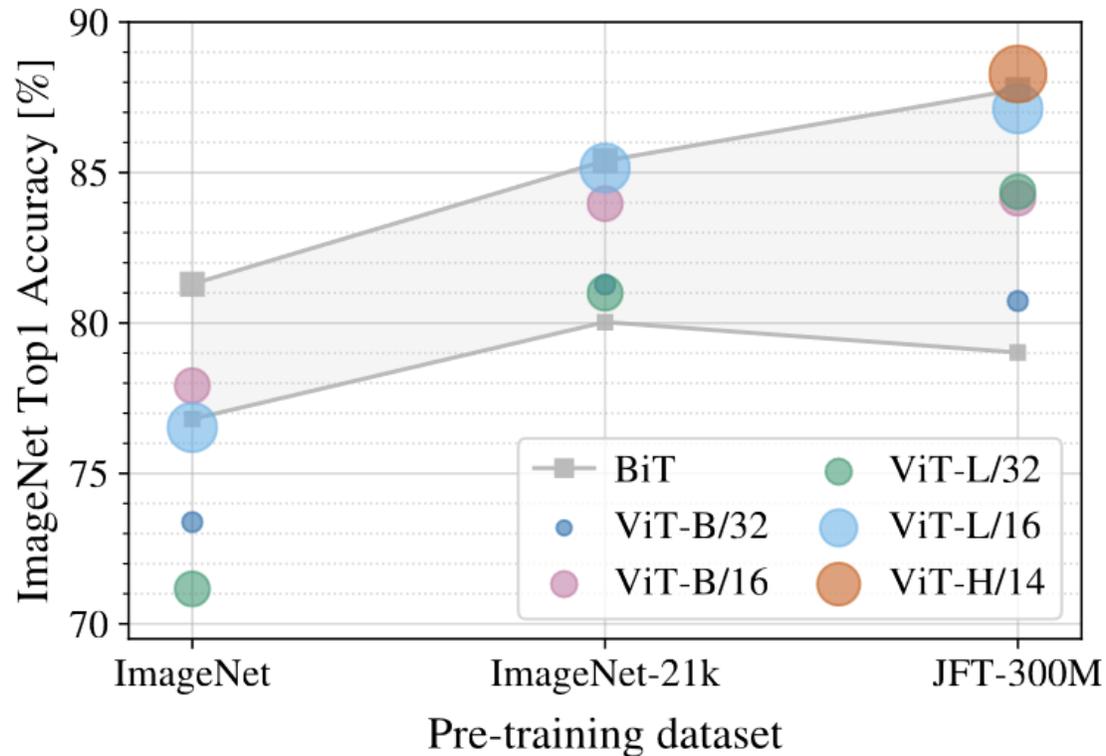

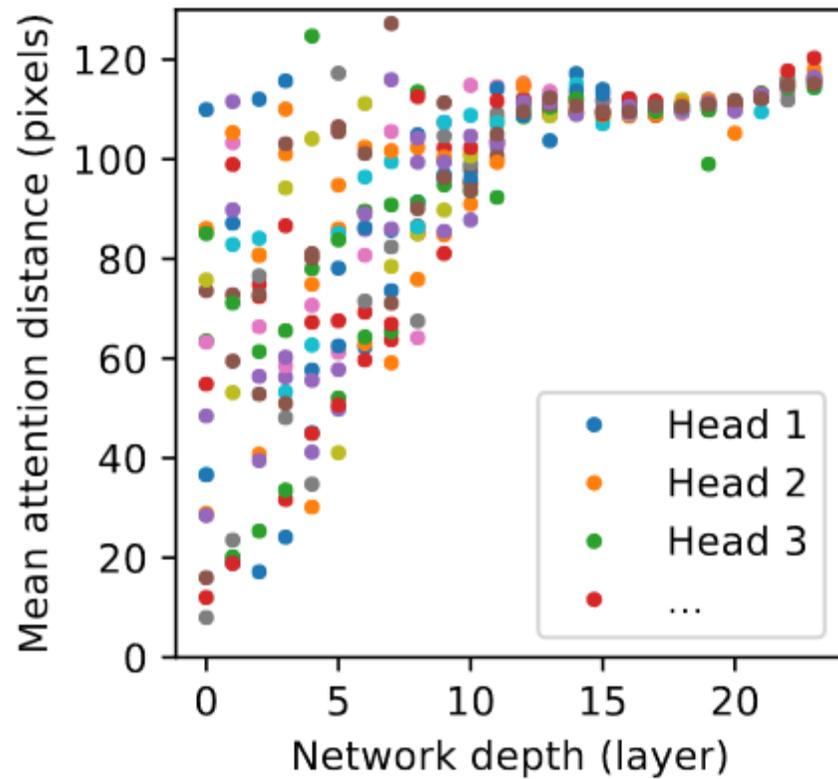

Figure 3: Transfer to ImageNet. While large ViT models perform worse than BiT ResNets (shaded area) when pre-trained on small datasets, they shine when pre-trained on larger datasets. Similarly, larger ViT variants overtake smaller ones as the dataset grows.

When trained on mid-sized datasets such as ImageNet, such models yield modest accuracies of a few percentage points below ResNets of comparable size. This seemingly discouraging outcome maybe expected: Transformers lack some of the inductive biases inherent to CNNs, such as translation equivariance and locality, and therefore do not generalize well when trained on insufficient amounts of data.

However, the picture changes if the models are trained on larger datasets (14M-300M images). We find that large scale training trumps inductive bias.

Summary

- “Attention” models outperform recurrent models and convolutional models for sequence processing and point processing. They allow long range interactions.
- Surprisingly, they seem to outperform convolutional networks for image processing tasks. Again, long range interactions might be more important than we realized.
- Naïve attention mechanisms have quadratic complexity with the number of input tokens, but there are often workarounds for this.

Reminder

- This is the final lecture. We won't use the reading period or the final exam slot.
- Project 5 is out and due Friday
- Project 6 is **optional**. It is due May 5th.
- The problem set will go out this week.

Thank you for making this semester work!
